GALAXIES

he dots and swirls that you see on this map are galaxies. It is thought that there could be as many as 100 billion galaxies in the Universe. When viewed through a strong telescope, we can see the shape of some of them. However, many others are so far away that their form is not clear.

LIGHT YEARS

18

Distances in space are so big that they can't be measured in the same way as on Earth. Otherwise the numbers would become mind-bogglingly huge. So instead, distances in space are measured in light years. In one year, light can travel approximately 9 trillion km - that's one light year. The square image above represents an area of the sky that is one million light years across, which is a really massive distance.

SPIRAL GALAXY COLOURS

Spiral-shaped galaxies come in many exciting colours. The centre is usually yellow-red, which means that it contains older stars that have cooled down. The arms of the spiral are usually bluish and include young or newborn stars.

BLUE GALAXIES

Blue galaxies often include lots of young and extremely hot stars. When captured on camera their images can appear red. This happens because their light changes as it travels through space.

two arms branching off

BARRED SPIRAL GALAXIES

Barred spiral galaxies have the ends of a bar-shaped structure that runs through their middle.

SPIRAL GALAXIES

These galaxies are composed of a central core surrounded by a disc of stars. This disc separates into long, curved 'arms'.

WHAT IS GRAVITY?

Gravity is one of the most important things in the universe - without it nothing would stay in place. It is a force that pulls objects together, and the strength of it depends on the mass of the objects. Mass is calculated by the amount of matter, or physical substance, an object has. Earth's gravity is quite strong, because it is a planet with a large mass. This means that everything on Earth, including you, is pulled towards its centre. The Moon's gravity, on the other hand, is much weaker. So if you were to jump upwards on the Moon, it would take much longer for you to be pulled back down. In space, all bodies (such as planets and moons) are pulled towards one another by gravity. This is what keeps planets in orbit around the Sun.
